# 1. Background

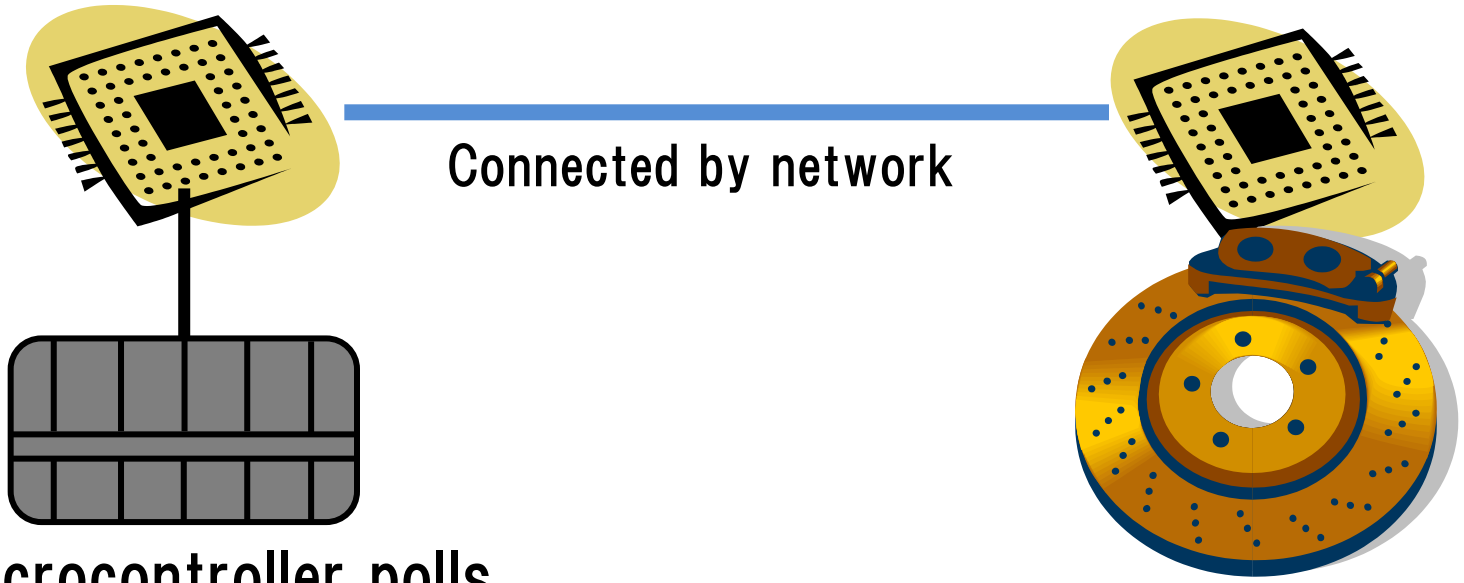
Yokohama Research Lab.
Linux Technology Center

# What is a Machine Control System?

HITACHI
Inspire the Next

A Realtime System reads and writes data at microsecond to millisecond intervals, to control physical machines

**Example: A brake system in a car**



A microcontroller polls the sensor value to detect how strong the pedal is pushed and sends the information over the network

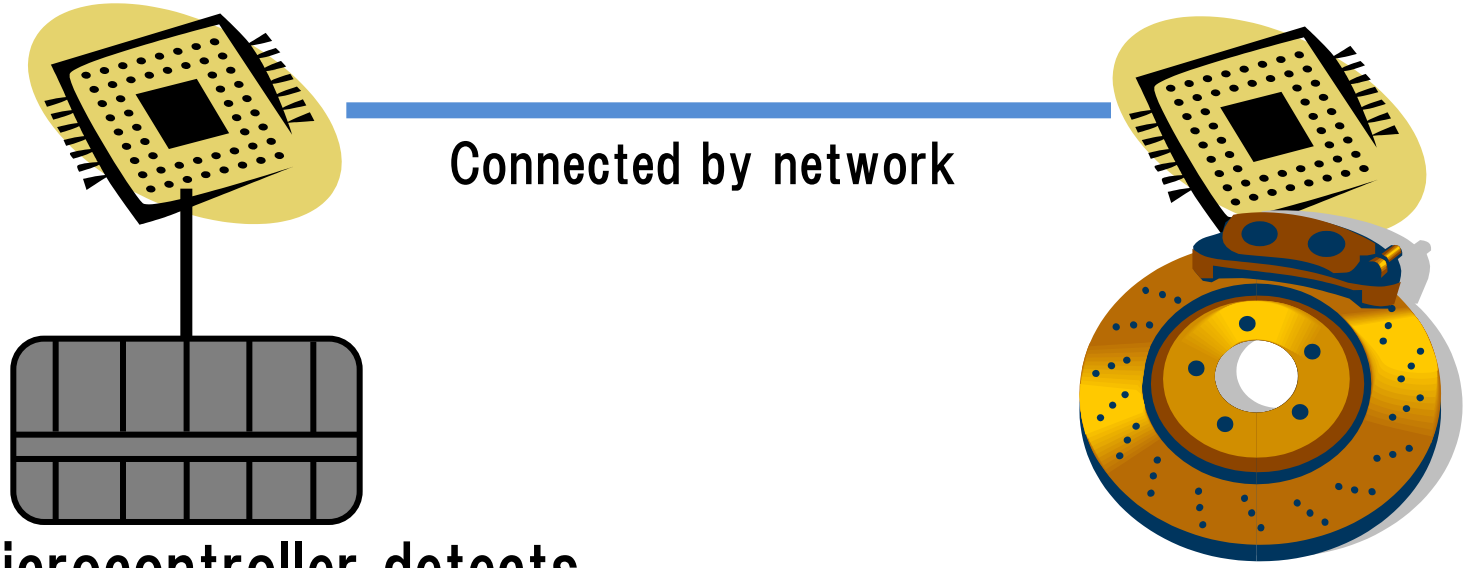
Another microcontroller receives the information and applies the brake

Yokohama Research Lab.
Linux Technology Center

# Problem without Realtimeness

HITACHI
Inspire the Next

## Example: A brake system in a car



If the microcontroller detects a push of pedal with some delay because of other programs, sending the information is also delayed.

Detection of the sensor value and applying brake is also delayed.

**It takes longer to apply brake after the brake pedal is pushed.**

**Braking Distance Gets Longer**

**Danger**

# Issues of Machine Control System Development

HITACHI
Inspire the Next

**Issues: Too large variety of environments for development**
**Linux can be used as the single unified environment**

## Current Machine Control Systems Development

- Use of different OSes for different products, or even no OS
  - VxWorks, FreeRTOS, μITRON, μT-Kernel etc.
- Issues
  - Small number of application developers for each OS
  - Difficult to acquire solid know-how
  - No middleware or network stack (or proprietary if available)

With Linux

The Issues are solved

- Lots of application developers for Linux
- Linux know-how is easier to acquire
- Multiple middleware and network stacks are included in Linux

Applying Linux to Machine Control Systems still has other issues

Yokohama Research Lab.
Linux Technology Center

# Issues of applying Linux to Embedded Systems

HITACHI
Inspire the Next

**Lack of realtimeness, and disk and memory usage are the issues.**

Linux is good at batch loads that process large amount of data.
Linux is originally for PCs. PCs have faster CPUs and larger memory and disks, compared to Machine Control Systems.

| | | |
|---|---|---|
| Issues | Lack of realtimeness | Memory and disk usage |
| Solutions | A mechanism to respond faster to the external inputs (PREEMPT_RT)<br><br>A mechanism to place code and data used in IRQ in SRAM | Linux for small controllers (uClinux) |

HITACHI
Inspire the Next

- Huge patchset
  - Making in-kernel locking-primitives (using spinlocks) preemptible through reimplementation with rtmutexes.
  - Implementing priority inheritance for in-kernel spinlocks and semaphores.
  - Converting interrupt handlers into preemptible kernel threads.

- Huge patchset / distoribution
  - “Mu” stands for “micro”, and “C” is for “controller”.
  - Name of the patchset suitable for NO MMU micro controllers.
  - Name of the distribution which includes a userland library and basic commands.

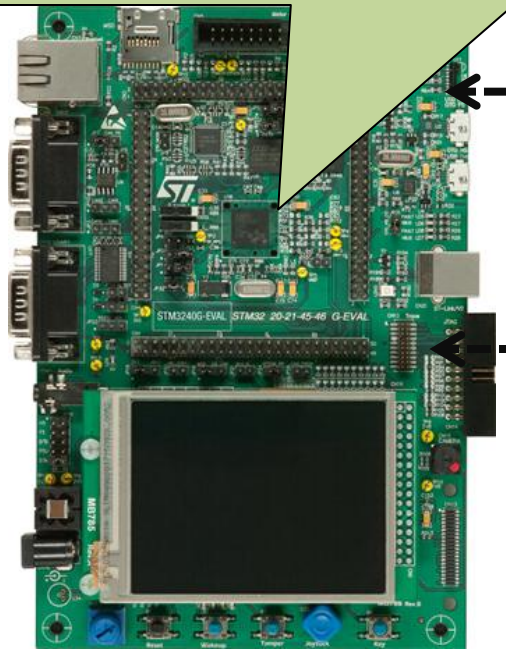
# My evaluation environment

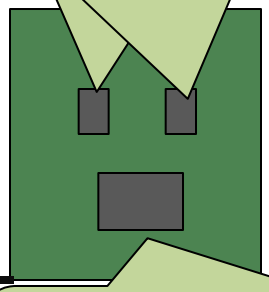
HITACHI
Inspire the Next

- Linux STM3240G-EVAL Kit made by EMCRAFT

SoC: STM32F407IG
CPU: ARM Cortex-M4 168MHz
SRAM: 192KB

Memory: PSRAM 16MB × 2
**Used as main memory**





Storage: NOR FLASH 8MB
**Bootimage is stored here**

**STMicroelectronics**
**STM3240G-EVAL Board**

**STM-MEM**
**plug-in board**

- **uClinux and BSP(Board Support Package) are available based on 2.6.33**

# Lack of drivers for peripherals

HITACHI
Inspire the Next

- In general…
  - BSPs(board support packages) are developed out of tree; have just a small amount of users; are not mature.
  - Users should evaluate if its functions and quality are satisfactory before working on it.
- In my evaluation…
  - hrtimer is necessary for realtime application but not available on evaluation environment
    - “STM32 System Timer” in SoC is used as clockevent. However, “oneshot mode” was not implemented.
    - “oneshot mode” is necessary for hrtimer.
    - I implemented “oneshot mode” and made hrtimer available.

# Difficulty of applying multiple huge patchset

HITACHI
Inspire the Next

- In general…
  - Each patchset can be applied onto a certain version of vanilla kernel.
  - Patchsets are not designed to be used with other patchsets.
- In my evalutation…
  - I applied PREEMPT_RT patch on BSP which included uClinux then many hunks were rejected.
  - I applied rejected hunks manually.
  - I hope that  at least one patchset will be upstreamed.
    - and the other one will be compatible with the upstreamed one.

# Unsuitability of in-kernel debugging tools

HITACHI
Inspire the Next

- In general…
  - Many in-kernel debug tools are unsuitable for uClinux running in Cortex-M
    - In-kernel debug tools are too heavy for Cortex-M
    - Some of the tools depend on architecture specific functions
- In my evaluation…
  - ftrace was too heavy.
  - IRQ tracer did not seem to work.
  - I had to “reinvent” necessary debugging tools.
    - I implemented a simple tracer which stores traces in SRAM.

# Evaluation of PREEMPT_RT, uClinux and environment

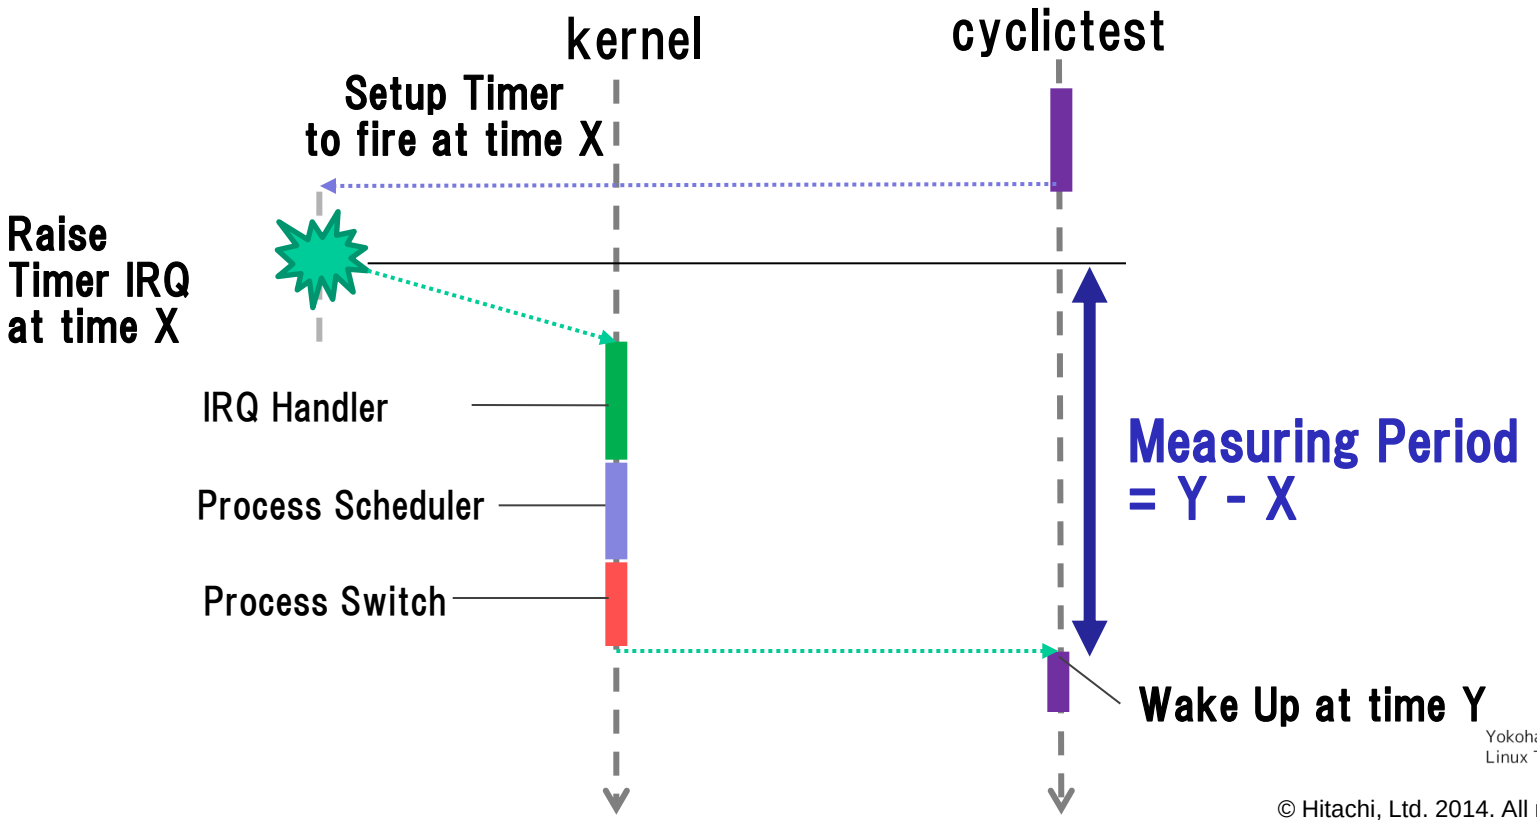
- Evaluation1: Cyclictest
- Evaluation2: Memory Access

Yokohama Research Lab.
Linux Technology Center

# Cyclictest

HITACHI
Inspire the Next

- For realtime applications, latency of timer IRQ response is very important
  - Realtime applications use timer to implement periodical procedures.



Yokohama Research Lab.
Linux Technology Center

# Result of Cyclictest (1/3)

HITACHI

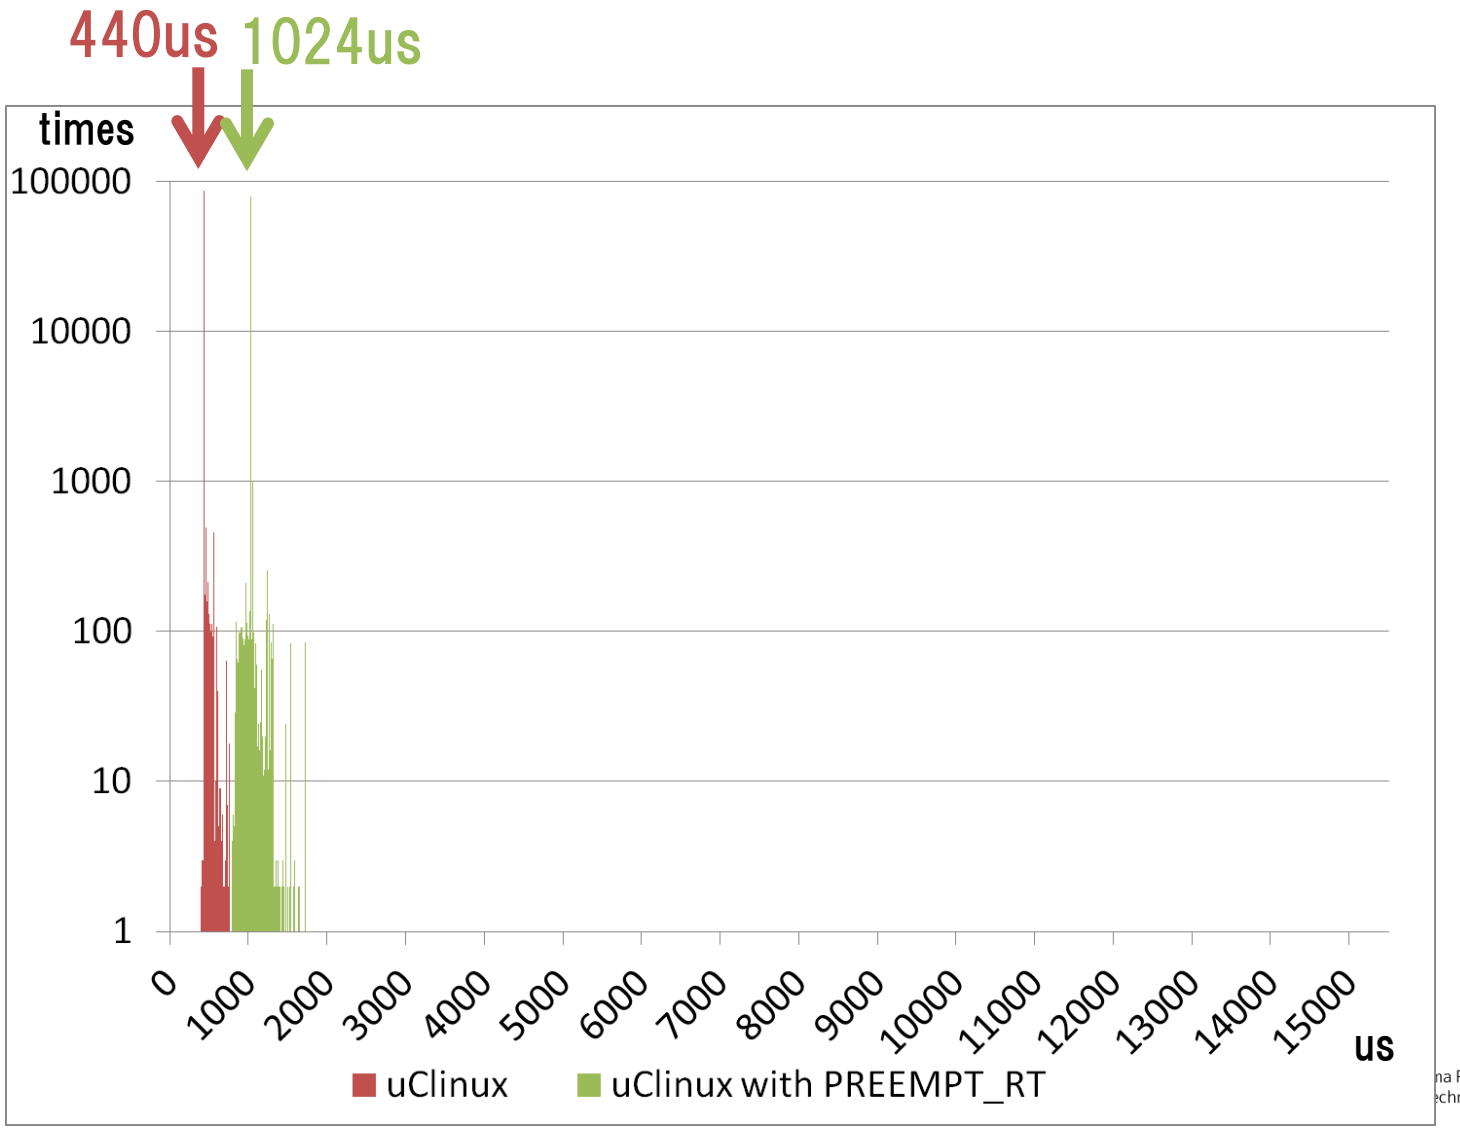
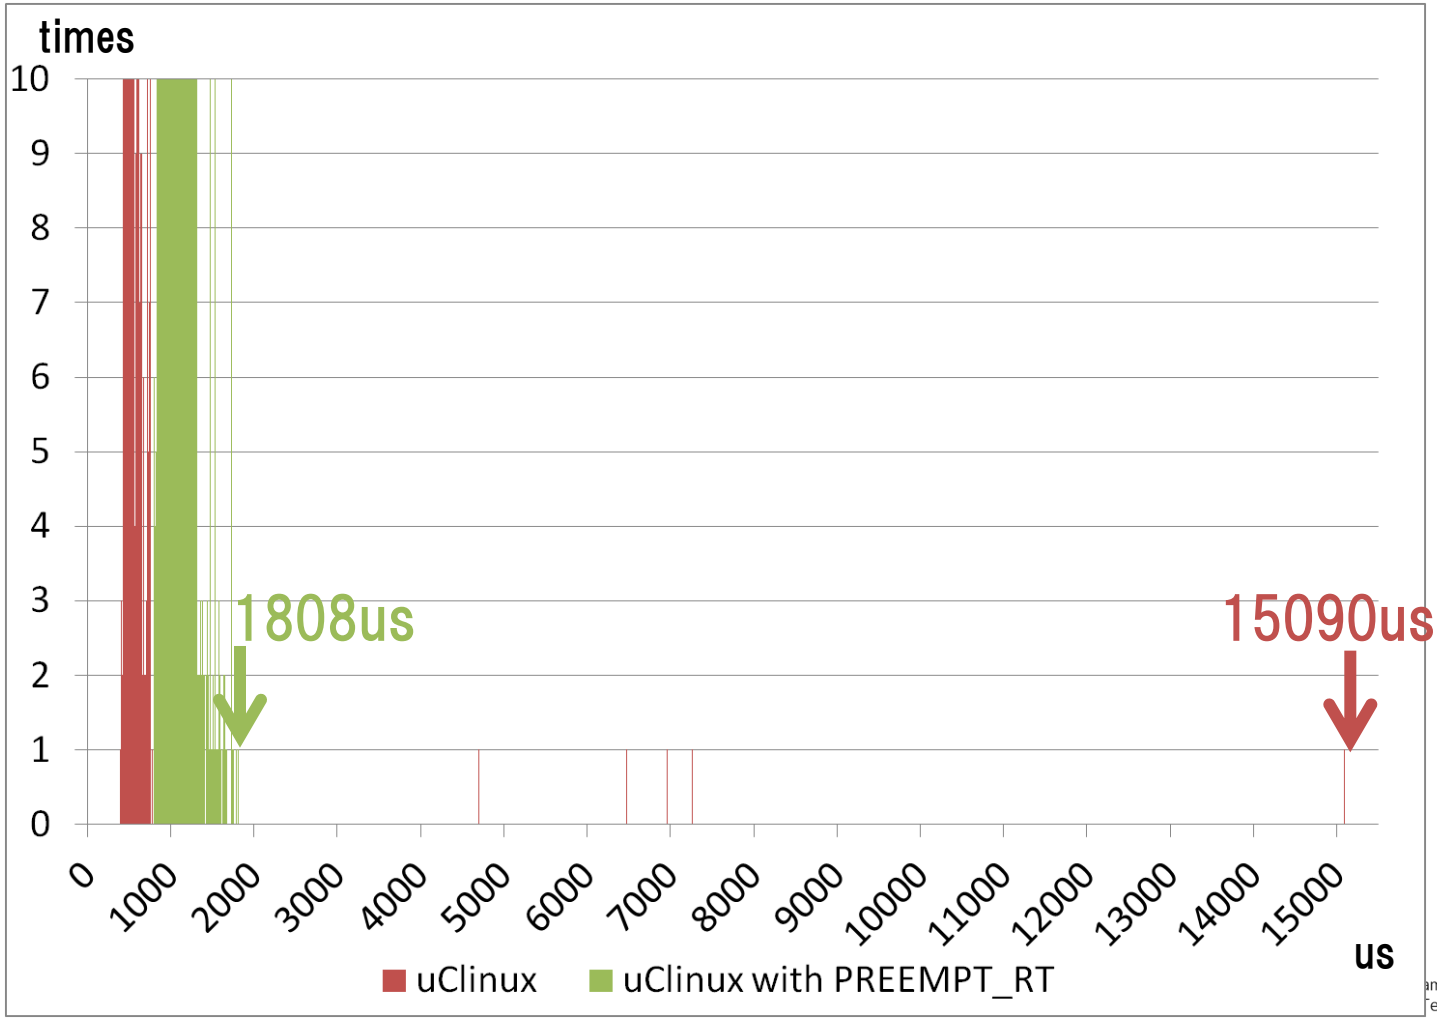
## Average



# Result of Cyclictest (2/3)

HITACHI
Inspire the Next

## Max Latency



ama Research Lab.
Technology Center

# Result of Cyclictest (3/3)

HITACHI
Inspire the Next

- Max latency is very important for realtime systems because developers have to define deadlines for periodical procedures.
- uClinux is better in worst case with PREEMPT_RT than without it.

| | uClinux | uClinux with PREEMPT_RT |
|---|---|---|
| Average | 440us | 1024us |
| Worst case | 15090us | **1808us** |

Yokohama Research Lab.
Linux Technology Center

# Memory Access PSRAM vs SRAM

HITACHI
Inspire the Next

- In my evaluation environment, uClinux run in PSRAM on the plug-in board.
- The SoC has just 192kb SRAM. This is too small to run uClinux.

- PSRAM on plug-in board is far slower than SRAM in SoC.
- If code and data used in IRQ context are placed in SRAM, IRQ latency will be lower.

# Result of Memory Access PSRAM vs SRAM

HITACHI
Inspire the Next

- Evaluated how much faster is SRAM than PSRAM in my environment.
  - Used own micro benchmark, which just dose 10M integer additions in-memory.

| | Code is stored in | Data is stored in | Time (Shorter is better) |
|---|---|---|---|
| Case 1 | PSRAM | PSRAM | 12047511 us |
| Case 2 | PSRAM | SRAM | 10430945 us |
| Case 3 | SRAM | PSRAM | 2396412 us |
| Case 4 | SRAM | SRAM | 651154 us |

about 20 times faster

  - If all the code and data of the IRQ context are placed in SRAM, timer IRQ latency will be probably 20 times lower.
  - Then max latency will be 90us instead of 1808us.

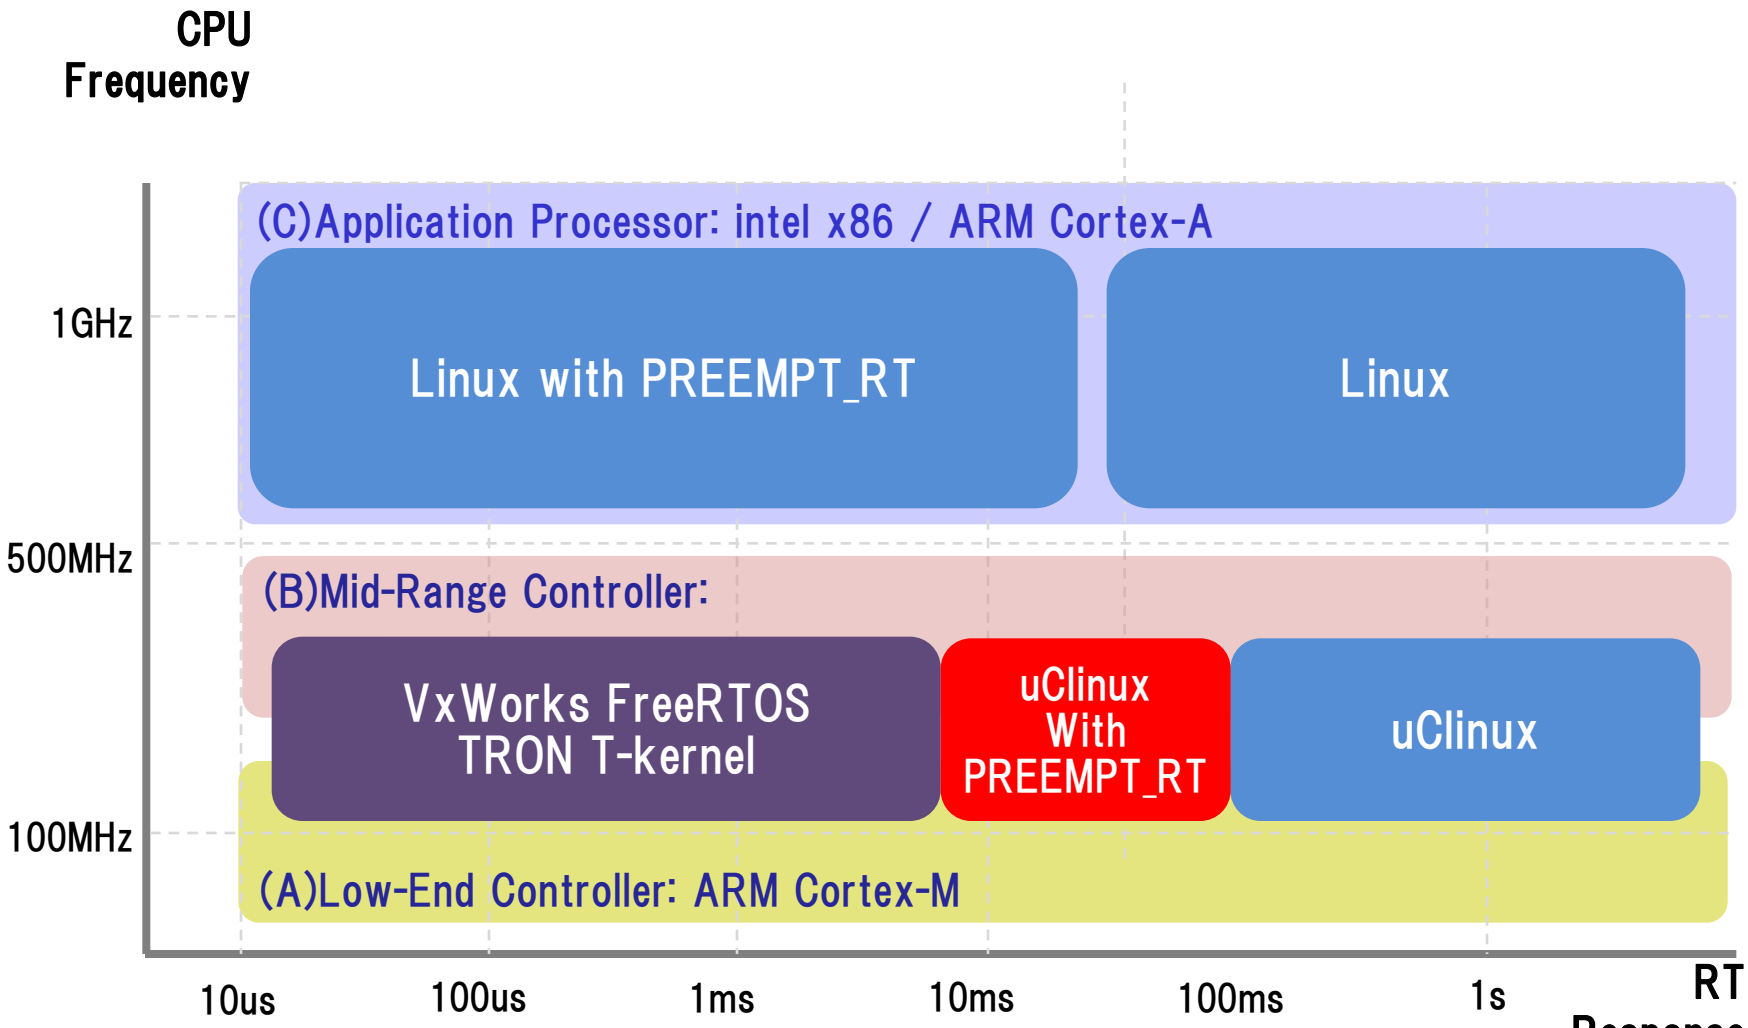
# Conclusion

Yokohama Research Lab.
Linux Technology Center

# Coverage of Linux after my Challenge

HITACHI
Inspire the Next



Yokohama Research Lab.
Linux Technology Center

# Conclusion

HITACHI
Inspire the Next

- uClinux's IRQ latency is shorter with PREEMPT_RT
  - Cyclictest showed that max latency was 1808us
  - Combination of uClinux and PREEMP_RT is useful for developing Machine Control Systems.
  - Max latency could be 90us if we would use SRAM for code and data of IRQ context.
- It's very tough to apply both uClinux and PREEMPT_RT.
  - In-kernel debugging tools are too heavy for Cortex-M.
  - Upstreaming is important for ease of use.

# Microbenchmark

HITACHI
Inspire the Next

```
int readfunc(void *addr, int length, int loop){
        int ret = 0;
        void *i;
        void *end;

        end = addr + length;
        while(loop-- > 0){
                for(i=addr; i<end; i++){
                        ret += *(char*)i;
                }
        }
        return ret;
}
```
